Abstract

The efficient operation of heating systems relies heavily on accurate temperature monitoring. However, such systems are vulnerable to data corruption, which can lead to erroneous temperature readings and potentially hazardous conditions. We propose a novel approach to address this challenge by employing machine learning techniques for spam detection and correction in heater temperature data for the detection phase.

We explore various machine learning algorithms including spam detection and classification models, to identify spam temperature readings. These models are trained on the preprocessed dataset and evaluated using appropriate metrics to assess their performance.

Keywords: Spam Detection, Temperature Control, Heater Systems, Python, Machine Learning, Linear Regression.

1. Introduction

In modern heating systems, maintaining precise temperature control is essential for efficiency and comfort. In this research paper, we propose a novel approach to smart spam detection and correction for temperature monitoring in heaters using python machine learning techniques. Machine learning offers a powerful toolkit for identifying patterns and spam in large datasets, making it well-suited for this task. Traditional methods of spam detection often rely on predefined thresholds or simple statistical measures, which can be insufficient in handling complex and dynamic environments typical of heating systems. Machine learning algorithms, on the other hand, can learn from historical data, adapt to new patterns, and provide more accurate and reliable detection and correction mechanisms. In the context of heating systems, temperature spam can have severe consequences, such as increased energy consumption, equipment damage, and reduced comfort levels. Moreover, incorrect temperature readings can also lead to inaccurate diagnoses and inefficient maintenance procedures. Therefore, it is essential to develop effective methods to detect and correct temperature spam in real-time. Existing methods for detecting spam data in smart heaters typically rely manual inspection or rulebased

filtering, which can be time-consuming and prone to errors. These methods may not be effective in detecting complex patterns of spam data. The significance of this research in its potential to revolutionize temperature monitoring systems in various domains, including residential and industrial heating applications. By mitigating the impact of spam data, our proposed solution not only improves temperature control but also reduces energy consumption and maintenance costs. The contributions of this paper:

1. We propose a machine learning-based approach for detecting spam data in smart heaters, which can improve the accuracy and reliability of temperature readings.
2. We develop a correction algorithm that can adjust the temperature readings based on the detected spam data, ensuring that the heating system operates efficiently and safely.

2. Literature Survey

2.1. Spam

The heater adjusts its power output based on the temperature of the room. When the room temperature is lower than the set point, the heater will increase power output to heat the room faster. As the room temperature approaches the set point, the heater will

gradually decrease its power output to maintain the set temperature.

2.2. The Benefits of Spam Include

1. **Faster Heating:** By increasing power output when the room is cold, spam helps to heat the room quickly.
2. **Energy Efficiency:** By adjusting power output based on temperature, spam can help reduce energy consumption and minimize standby losses.
3. **Improved Temperature Control:** Spam helps to maintain a consistent temperature by adjusting power output to match changing room conditions.

2.3. Spam Detection and Correction

The involves looking into existing methods, algorithms and techniques used for spam detection and correction in various domains such as email, social media, heater, or other communication channel.

2.4. Temperature Control in Heaters

Exploring literature related to temperature control systems, especially in heaters or similar devices, will provide insights into different control strategies, feedback mechanisms and algorithms used to maintain or regulate temperature effectively and efficiently.

2.5. Python Machine Learning

Reviewing literature on machine learning techniques and algorithms implemented using python will provide a foundation for understanding the tools and methodologies available for building machine learning tools. This includes exploring topics such as classification, regression, clustering and NLP, among others.

2.6. Integration of Machine Learning in Temperature Control

Investigating studies that have applied machine learning techniques to temperature control systems or similar domains can offer valuable insights into the challenges, opportunities and best practices for integrating machine learning into such systems.

3. Methodology

The spam detection and correction for temperature in heater using machine learning algorithm

3.1. Software

For implementing this project using python machine

learning, I have used jupyter notebook in python software and various libraries. Python is the primary programming language used for machine learning project due to its simplicity, readability, and the availability of numerous libraries for data manipulation, visualization, and machine learning model development.

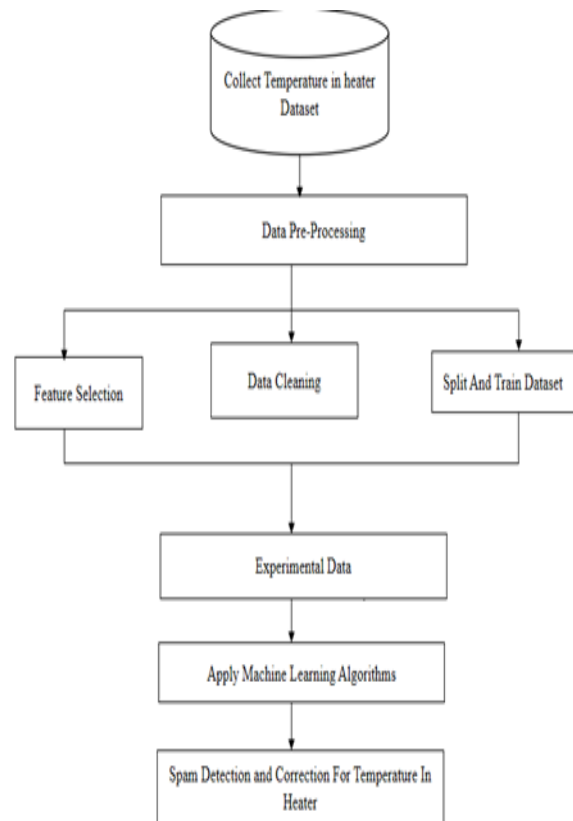

Figure 1 Flowchart of Spam Detection in Temperature in Heater

We start with spam detection and correction for temperature in heater data This is shown in figure.1 according to the above flow. After the data has been collected, we have train our machine learning model using the data they are not directly applicable to our project. To accomplish this our data needs to be preprocessed. Following that, I have split our data into training and test data, which will be used in training and evaluating our Spam model. Once I have done that, I have feed data into our Linear Regression model. [1]

3.2. Importing Libraries

I have started by first imported libraries I have been used shown in figure.2. Using matplotlib you can plot

graphs, histogram and bar plot. Pandas for data manipulation and analysis, Numpy is to do the mathematical and scientific operation. [2] Seaborn is used for making statistical graphics more attractive and informative. Statsmodels is used for statistical modeling and hypothesis testing.

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
import statsmodels.api as sm
```

Figure 2 Packages

4. Data Collection

Collect a dataset of temperature readings from the heater, along with corresponding labels indicating whether the reading is normal or spam.

4.1. Dataset

The dataset used in this research paper is available on Kaggle this dataset shown in figure 3.

```
[4]: # Import Dataset
[1]: import pandas as pd
df = pd.read_csv("Temperature_heater_dataset.csv")
[6]: df.head(5)
```

	Time (s)	CO (ppm)	Humidity (%r.h.)	Temperature (C)	Flow rate (ml/min)	Heater voltage (V)	R1 (MOhm)	R2 (MOhm)	R3 (MOhm)	R4 (MOhm)	R5 (MOhm)	R6 (MOhm)	R7 (MOhm)	R8 (MOhm)	R9 (MOhm)	R10 (MOhm)	R11 (MOhm)	R12 (MOhm)	R13 (MOhm)	R14 (MOhm)

5. Data Preprocessing

Clean and preprocess the data for analysis. This might involve handling missing values, normalizing the data and labeling the data if necessary.

5.1. Data Cleaning

5.1.1. Handling Missing Values

Handling missing values this is shown in figure 4 for demonstration and filled them using the rolling mean of temperature column.

```
[9]: #check for missing values in dataset
[10]: df.isnull().sum()
[10]: Time (s) 0
CO (ppm) 0
Humidity (%r.h.) 0
Temperature (C) 0
Flow rate (ml/min) 0
Heater voltage (V) 0

```

Figure 8 Separate Target Variable

6. Splitting Training and Testing Data

The next part is the most important since we used one set of data to test our model and another set to evaluate it. In other words, part of the X will be our training data, and the other part will be our test data. The same applies to Y. [3]

6.1. Training Dataset

This training dataset shown in figure.9 will be used to train the machine learning model to detect and correct spam temperature readings. It should include a sufficient number of normal and spam temperature readings. A common split is around 70-80% of the data for training.

```
[17]: # split x and y data into training and testing set
from sklearn.model_selection import train_test_split
x_train,x_test,y_train,y_test = train_test_split(x,y, test_size = 0.2, random_state = 0)
[18]: x_train
```

Figure 10 Testing Dataset

6.3. Model Training

Using linear regression to train the model based on the preprocessed data to learn patterns and relationships between a dependent variable and one or more independent variables this shown in figure 11.

```
[51]: # Model fitting
[58]: # train a linear regression model on the training set
from sklearn.linear_model import LinearRegression
# Define the model
model = LinearRegression()
# fit the model
model.fit(x_train_const, y_train)
[59]: LinearRegression
LinearRegression()
```

Figure 11 Model Training

6.4. Compare Train and Test Set Accuracy

It's essential to evaluate the performance of your model on both the training data and the testing data. This is because the training data is used to train the model, while the testing data is used to evaluate its performance on unseen data.

Accuracy Formula:

Accuracy is a measure of how well your model predicts the correct output this shown in figure.12.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN}$$

Where:

- TP = True Positives (correct predictions)
- TN = True Negatives (correct predictions)
- FP = False Positives (incorrect predictions)
- FN = False Negatives (incorrect predictions)

```
[ ]: # Compare the train-set and test-set accuracy
[40]: y_pred_train = model.predict(x_train)
      y_pred_train
[40]: array([34959.89614237, 73800.23720063, 60778.80737922, ...,
          27926.43061417, 67402.45054057, 23661.85604638])
```

Figure 12 Train and Test Set Accuracy

6.5. Training and Test Set Accuracy Score

The accuracy score is a measure of how well your machine learning model performs on the test set. This is shown in figure.13. It's the proportion of correctly classified instances (correct/incorrect temperature readings) out of the total number of instances in the test set.

Formula:

$$\text{Accuracy} = \frac{TP+ TN}{(\text{Total Samples})}$$

Where:

1. True Positives (TP) = Correctly classified correct temperature readings.
2. True Negatives (TN) = Correctly classified incorrect temperature readings.
3. True Samples = Total number of instances in the test set.

```
[ ]: # print the scores on training and test set
[25]: print('Training set score: {:.4f}'.format(model.score(x_train, y_train)))
      print('Test set score: {:.4f}'.format(model.score(x_test, y_test)))
      Training set score: 0.4411
      Test set score: 0.4382
```

Figure 13 Accuracy Score

6.6. Confusion Matrix

A confusion matrix is a matrix the summarizes the performance of a machine learning model on a set of test data. It is means of displaying the number of accurate and inaccurate instances based on the model's predictions. It is often used to measure the performance of classification models, which aim to predict a categorical label for each input instance. The specific table layout that allows visualization of the performance of an algorithm, typically a supervised learning model. It is used for classification problems where the output can be two or more classes. The matrix itself is a square table with dimensions equal to the number of classes in the classification problem. this confusion matrix shown in figure.14. Confusion matrix is a very good way to understand results like true positive, false positive, true negative and so on [4].

Figure 14 Confusion Matrix

6.7. Precision & Recall

Precision it is ratio of true positive predictions to the total predicted positives.

$$\text{Precision} = \frac{TP}{(TP+FP)}$$

Recall It is the ration of true positive predictions to the total actual positives.

$$\text{Recall} = \frac{TP}{(TP+FN)}$$

- TP = True Positive
- FP = False Positive
- TN = True Negative
- FN = False Negative
- Precision = 99%
- Recall = 91.3%

7. Machine Learning Algorithm

I have used linear regression algorithm in this project.

7.1. Linear Regression

Linear regression is a type of supervised machine

learning algorithm that computes the linear relationship between the dependent variable and one or more independent features by fitting a linear equation to observed data [5]. When there is only one independent variable, it is known as Simple Linear Regression and when there are multiple independent variables, it is known as Multiple Linear Regression. A supervised machine learning algorithm that learns from the labelled dataset and maps the data points to the most optimized linear functions. Which can be used for predictions on new dataset [6].

Classification: It predicts the class of the dataset based on the independent input variable, class is the categorical or discrete values [7].

Regression: It predicts the continuous output variables based on the independent input variable, like the predictions of spam mail [8-10].

7.2. Types of Linear Regression

7.2.1. Simple Linear Regression

This is the simplest form of linear regression, and it involves only one independent variable and one dependent variable. The equation for simple linear regression is:

$$Y = \beta_0 + \beta_1 X$$

Where:

- Y is the dependent variable
- X is the independent variable
- β_0 is the intercept
- β_1 is the slope

7.2.2. Multiple Linear Regression

This involves more than one independent variable and one dependent variable. The equation for multiple linear regression is [11]:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_n X_n$$

Where:

- Y is the dependent variable
- X_1, X_2, \dots, X_p are the independent variables
- β_0 is the intercept
- $\beta_1, \beta_2, \dots, \beta_n$ are the slopes

8. Calculate Spam in Temperature

Calculate the spam in temperature based on the provided variables we'll denote the spam in temperature as T which is the difference between the maximum and minimum temperature.

8.1. Identify Variables

- CO: carbon monoxide concentration
- H: Humidity
- T: Temperature
- F: Flowrate
- V: Heater Voltage
- R: Resistance
- R_i : Values of resistors
- β_0 : Intercept
- $\beta_1, \beta_2, \dots, \beta_{5+n}$: Coefficients for each independent variable

ϵ : Error term

8.2. General Linear Model for Temperature

Assuming a linear relationship (which can be modified if the relationship is known to be non-linear):

$$T = \beta_0 + \beta_1 \cdot CO + \beta_2 \cdot H + \beta_3 \cdot F + \beta_4 \cdot V + \beta_5 \cdot R + \sum_{i=1}^n \beta_{5+i} \cdot R_i + \epsilon$$

8.3. Spam Calculation

The spam of temperature T is given by:

$$T = [T]_{\max} - [T]_{\min}$$

8.3.1. Determining $[T]_{\max}$ and T_{\min}

To find $[T]_{\max}$ and T_{\min} calculates the temperature using the maximum and minimum values of each variable.

Then,

$$T_{\max} = \beta_0 + \beta_1 \cdot CO_{\max} + \beta_2 \cdot H_{\max} + \beta_3 \cdot F_{\max} + \beta_4 \cdot V_{\max} + \beta_5 \cdot R_{\max} + \sum_{i=1}^n \beta_{5+i} \cdot [R_i]_{\max} + \epsilon$$

$$T_{\min} = \beta_0 + \beta_1 \cdot CO_{\min} + \beta_2 \cdot H_{\min} + \beta_3 \cdot F_{\min} + \beta_4 \cdot V_{\min} + \beta_5 \cdot R_{\min} + \sum_{i=1}^n \beta_{5+i} \cdot [R_i]_{\min} + \epsilon$$

9. Result and Discussion

In this session, all the results are presented in graph, tables. All the results are discussed in detail. This code that the dataset is stored in csv files named dataset.csv. This CSV file shown in figure.15. The code loads the data, defines the features and target variable, create a linear regression model, fits the model to each dataset, predicts the temperature for each dataset, calculate the error term and spam or not spam classification for each dataset, and saves the results to a CSV file. Finally, it evaluates the accuracy of the model using the accuracy_score function from scikit_learn [12].

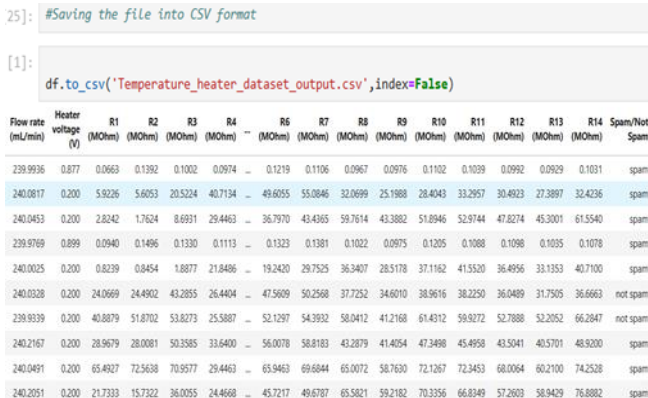

Figure 15 CSV File Spam Not Spam

Conclusion

The conclusion is that algorithm can be used to classify whether a given temperature reading is spam or not spam based on a linear regression model that takes into account several factors. The algorithm can be trained on dataset and then used to predict whether new temperature readings are spam or not spam. This script automates the process of calculating the temperature, classifying the data, and saving the results to new csv files. You can adjust the coefficients and threshold as needed for your specific application.
